

PDO Threads

With ageing, skin sagging occurs due to ligaments laxity, volume loss, bone resorption and reduced skin elasticity. PDO Thread treatment lifts and tightens sagging skin tissue, using threads made of Polydioxanone (PDO). PDO threads are absorbable and tissue friendly filaments.

They are made of strong filament fiber, consisting of a few twisted fiber threads, which naturally dissolves after 4-6 months. They are inserted with a special technique to integrate into sub-dermal layer of skin then pulling them in specific directions, creating instant results.

This technique also encourages natural collagen production. The procedure requires topical numbing or freezing using numbing agents injection.

Dr AK learned this special procedure in US and have attended several training courses and work-shops. Over the past 4 years, he had built a growing number of satisfied patients across GTA.
